

BASES FOR SPACES OF HIGHEST WEIGHT VECTORS IN ARBITRARY CHARACTERISTIC

ADAM DENT AND RUDOLF TANGE

SUMMARY. Let k be an algebraically closed field of arbitrary characteristic. First we give explicit bases for the highest weight vectors for the action of $\mathrm{GL}_r \times \mathrm{GL}_s$ on the coordinate ring $k[\mathrm{Mat}_{rs}^m]$ of m -tuples of $r \times s$ -matrices. It turns out that this is done most conveniently by giving an explicit good $\mathrm{GL}_r \times \mathrm{GL}_s$ -filtration on $k[\mathrm{Mat}_{rs}^m]$. Then we deduce from this result explicit spanning sets of the $k[\mathrm{Mat}_n]^{\mathrm{GL}_n}$ -modules of highest weight vectors in the coordinate ring $k[\mathrm{Mat}_n]$ under the conjugation action of GL_n .

INTRODUCTION

Let k be an algebraically closed field, let GL_n be the group of invertible $n \times n$ matrices with entries in k and let T_n and U_n be the subgroups of diagonal matrices and of upper uni-triangular matrices respectively. The group $\mathrm{GL}_r \times \mathrm{GL}_s$ acts on the k -vector space Mat_{rs}^m of m -tuples of $r \times s$ matrices with entries in k via $((A, B) \cdot \underline{X})_i = AX_iB'$, where $\underline{X} = (X_1, \dots, X_m) \in \mathrm{Mat}_{rs}^m$ and B' is the transpose of B , and on the coordinate ring $k[\mathrm{Mat}_{rs}^m]$ via $((A, B) \cdot f)(\underline{X}) = f((A', B') \cdot \underline{X}) = f((A'X_iB)_{1 \leq i \leq m})$. For (μ, λ) a character of $T_r \times T_s$, the space of highest weight vectors will be denoted $k[\mathrm{Mat}_{rs}^m]_{(\mu, \lambda)}^{U_r \times U_s}$. It consists of the functions $f \in k[\mathrm{Mat}_{rs}^m]$ with $(A, B) \cdot f = f$ for all $(A, B) \in U_r \times U_s$ and $(A, B) \cdot f = \mu(A)\lambda(B)f$ for all $(A, B) \in T_r \times T_s$.

Our first goal in this paper is to give bases of the vector spaces $k[\mathrm{Mat}_{rs}^m]_{(\mu, \lambda)}^{U_r \times U_s}$. In [10] this was done under the assumption that k is of characteristic 0. The method there was to reduce the problem via a few simple isomorphisms to certain results from the representation theory of the symmetric group which were originally due to J. Donin. Although this method is rather straightforward, it is hard to generalise to arbitrary characteristic. In the present paper we solve the problem in arbitrary characteristic using results on bideterminants from the work of Kouwenhoven [8] which is based on work of Clausen [2], [3]. We introduce “twisted bideterminants” to construct an explicit “good” filtration and, in particular, give bases for the spaces of highest weight vectors in $k[\mathrm{Mat}_{rs}^m]$, see Theorem 1 and its two corollaries in Section 2. It turns out that these bases can also be obtained by dividing the basis elements from [10, Thm. 4] by certain integers in the obvious \mathbb{Z} -form and then reducing mod p .

As an application we give in Section 3 explicit finite homogeneous spanning sets of the $k[\mathrm{Mat}_n]^{\mathrm{GL}_n}$ -modules of highest weight vectors in the coordinate ring $k[\mathrm{Mat}_n]$ under the conjugation action of GL_n , see Corollary 4 in Section 3.

2010 *Mathematics Subject Classification.* 13A50, 16W22, 20G05.

Although this problem is difficult to tackle directly, we gave in [10] a method in arbitrary characteristic called “transmutation” to reduce this problem to giving spanning sets for the vector spaces $k[\text{Mat}_{rs}^m]^{U_r \times U_s}_{(\mu, \lambda)}$, see Theorem 2 in the present paper. So the problem is reduced to the problem we solved in Section 2.

1. PRELIMINARIES

The field k , the groups GL_n, U_n, T_n , the variety Mat_{rs}^m and its coordinate ring $k[\text{Mat}_{rs}^m]$ are as in the introduction. Note that $k[\text{Mat}_{rs}^m]$ is the polynomial algebra over k in the variables $x(l)_{ij}$, $1 \leq l \leq m$, $1 \leq i \leq r$, $1 \leq j \leq s$, where $x(l)_{ij}$ is the entry in the i -th row and j -column of the l -th matrix. If $m = 1$ we write x_{ij} instead of $x(1)_{ij}$. The $\text{GL}_r \times \text{GL}_s$ -module $k[\text{Mat}_{rs}^m]$ is multigraded by tuples of integers ≥ 0 (not necessarily partitions) of length m . We denote the set of such tuples with coordinate sum t by Σ_t . So the elements in the piece of multidegree $\nu \in \Sigma_t$ have total degree t .

1.1. Skew Young diagrams and tableaux. For λ a partition of n we denote the length of λ by $l(\lambda)$ and its coordinate sum by $|\lambda|$. We will identify each partition λ with the corresponding Young diagram $\{(i, j) \mid 1 \leq i \leq l(\lambda), 1 \leq j \leq \lambda_i\}$. The $(i, j) \in \lambda$ are called the *boxes* or *cells* of λ .

More generally, if λ, μ are partitions with $\lambda \supseteq \mu$, then we denote the diagram λ with the boxes of μ removed by λ/μ and call it the *skew Young diagram* associated to the pair (λ, μ) . Of course the skew diagram λ/μ does not determine λ and μ . For a skew diagram E , we will denote the transpose by E' and the number of boxes by $|E|$. The group of permutations of the boxes of E will be denoted by $\text{Sym}(E)$, and the column stabliser of E in $\text{Sym}(E)$, that is, the product of the groups of permutations of each column of E , will be denoted by C_E . By *diagram mapping* we mean a bijection between two diagrams as subsets of $\mathbb{N} \times \mathbb{N}$.

Let E be a skew diagram with t boxes. A *skew tableau* of shape E is a mapping $T : E \rightarrow \mathbb{N} = \{1, 2, \dots\}$. A skew tableau of shape E is called *ordered* if its entries are weakly increasing along rows and weakly increasing along columns, and it is called *semi-standard* if its entries are weakly increasing along rows and strictly increasing along columns. It is called a *t-tableau* if its entries are the numbers $1, \dots, t$ (so the entries must be distinct). A *t-tableau* whose entries are strictly increasing along both columns and rows is called *standard*. If m is the biggest integer occurring in a tableau T , then the *weight* of T is the m -tuple whose i -th component is the number of occurrences of i in T . Sometimes we will also consider the weight of T as an m' -tuple for some $m' \geq m$ by extending it with zeros.

For a skew shape E with t boxes, we define the *canonical* skew tableau S_E by filling the boxes in the i -th row with i 's, and we define the tableau T_E by filling in the numbers $1, \dots, t$ row by row from left to right and top to bottom. So S_E is semi-standard, and T_E is a *t-tableau* which is standard. The *standard enumeration* of a tableau T of shape E is the t -tuple obtained from T by reading its entries row by row from left to right and top to bottom.

Let μ be the tuple of row lengths of E , i.e. the weight of S_E . A semi-standard tableau S of shape F and weight μ is called *special* if $S = S_E \circ \alpha$ for

some diagram mapping $\alpha : F \rightarrow E$ such that for any $a, b \in F$, if $\alpha(b)$ occurs strictly below $\alpha(a)$ in the same column, then b occurs in a strictly lower row than a . We then say that α *represents* S . We call α *admissible* if for any $a, b \in F$, if $\alpha(b)$ occurs strictly below $\alpha(a)$ in the same column, then b occurs in a strictly lower row than a and in a column to the left of a or in the same column. By [10, Lem. 6] every special semi-standard tableau has an admissible representative. An admissible mapping α is called *special* if additionally, for any $a, b \in F$ with $\alpha(b)$ in a column strictly to the left of $\alpha(a)$, b occurs;

- (1) in a column strictly to the right of a and in a row above a or in the same row, if $\alpha(b)$ is in the same row as $\alpha(a)$;
- (2) in a column strictly to the right and of a a row strictly above a , if $\alpha(b)$ is in a row strictly above $\alpha(a)$;
- (3) in a column strictly to the right of a or in a strictly lower row, if $\alpha(b)$ is in a strictly lower row than $\alpha(a)$;

The diagram mapping α is special if and only if α^{-1} is special. Furthermore, $S_E \circ \alpha$ is semi-standard (and therefore special) whenever α is special and every special semi-standard tableau has a unique special representative.

Let P and Q be ordered tableaux of shapes E and F , both of weight $\nu \in \Sigma_t$. Then a diagram mapping $\alpha : F \rightarrow E$ with $P \circ \alpha = Q$ determines an m -tuple of tableaux $(S_{P^{-1}(1)} \circ \alpha_1, \dots, S_{P^{-1}(m)} \circ \alpha_m)$ (*), where $\alpha_i : Q^{-1}(i) \rightarrow P^{-1}(i)$ is the restriction of α to $Q^{-1}(i)$. We will say that α *represents* (*). Notice that the m -tuples (*), for varying α , all have the same tuple of shapes and the same tuple of weights. We express this by saying that the tuple of tableaux has *shapes determined by Q and weights determined by P* . When the tableaux $S_{P^{-1}(i)} \circ \alpha_i$ are special semi-standard, we require the α_i to be admissible. The above combinatorics is interpreted in the section below. For more detail see [10, Sect. 3], or [11], [12] where special diagram mappings are defined as “pictures”.

1.2. Bideterminants and skew Schur and Specht modules. Let S and T be (skew) tableaux of the same shape E , S with entries $\leq r$ and T with entries $\leq s$. Then we define the *bideterminant* $(S | T) \in k[\text{Mat}_{rs}]$ by

$$(S | T) = \prod_{i=1}^n \det((x_{S(a), T(b)})_{a, b \in E^i}),$$

where E^i is the i -th column of E and n is the number of columns in E . Note that we have

$$(S | T) = \sum_{\pi \in C_E} \text{sgn}(\pi) \prod_{a \in E} x_{S(\pi(a)), T(a)} = \sum_{\pi \in C_E} \text{sgn}(\pi) \prod_{a \in E} x_{S(a), T(\pi(a))},$$

where $C_E \leq \text{Sym}(E)$ is the column stabiliser of E .

As is well-known, the elements $(S | T)$, S standard with entries $\leq r$ and T standard with entries $\leq r$ form a basis of $k[\text{Mat}_{rs}]$, see [5]. In fact one can use bideterminants to construct explicit “good” filtrations of $k[\text{Mat}_{rs}]$ as a $\text{GL}_r \times \text{GL}_s$ -module, see [4].

The *skew Schur module* associated to a shape E , denoted by $\nabla_{\text{GL}_r}(E)$, is the span in $k[\text{Mat}_{rs}]$, $s \geq$ the number of rows of E , of all the bideterminants $(S | S_E)$ where S is a tableau of shape E and with entries $\leq r$. The skew Schur module

$\nabla_{\mathrm{GL}_r}(E)$ will be nonzero if and only if r is \geq the length of each column of E . It can easily be seen that $\nabla_{\mathrm{GL}_r}(E)$ is GL_r -stable, and it is well-known that the set of bideterminants $(S | S_E)$ with S as above and in addition semi-standard form a basis. Note that if E is an ordinary Young tableau then $\nabla_{\mathrm{GL}_r}(E)$ is the Schur (or induced) module associated to it. The *co-Schur* or *Weyl module* $\Delta_{\mathrm{GL}_r}(E)$ associated to a shape E can be defined as the contravariant dual $\nabla_{\mathrm{GL}_r}(E)^\circ$ which is the dual of the vector space $\nabla_{\mathrm{GL}_r}(E)$ with GL_r acting via the transpose: $(g \cdot f)(v) = f(g' \cdot v)$, where g' is the transpose of $g \in \mathrm{GL}_r$. If E, F, μ are as in Section 1.1, then the number of special semi-standard tableaux of shape F and weight μ is equal to the dimension of $\mathrm{Hom}_{\mathrm{GL}_r}(\Delta_{\mathrm{GL}_r}(F), \nabla_{\mathrm{GL}_r}(E))$ whenever r is \geq the number of rows of E or \geq the number of rows of F . This can be seen by reducing to the case that k has characteristic 0 using [9, Prop. II.4.13], and then using standard properties of skew Schur functions. For more details we refer to [1] and [8].

Drop for the moment the assumption that k is algebraically closed. The *skew Specht module* $S(E) = S_{t,k}(E)$ for the group algebra $A = A_{t,k} = k\mathrm{Sym}_t$ of the symmetric group Sym_t on $\{1, \dots, t\}$ is defined just as in the case of an ordinary Young diagram: $S(E) = Ae_1e_2$, where e_1 is the column anti-symmetriser of T_E and e_2 is the row symmetriser of T_E . The module $M(E) = M_{t,k}(E) = Ae_2$ is called the *permutation module* associated to E . One can also define $S_{t,k}(E)$ as the weight space $\nabla_{\mathrm{GL}_r}(E)_{1^t}$ for any $r \geq t$. Note that this weight space is indeed stable under $\mathrm{Sym}_t \leq \mathrm{GL}_r$. Now assume k is of characteristic 0 and let E, F, μ be as in Section 1.1. Then the number of special semi-standard tableaux of shape F and weight μ is equal to the dimension of $\mathrm{Hom}_{\mathrm{Sym}_t}(S(E), S(F)) \cong (S(E) \otimes S(F))^{\mathrm{Sym}_t} \cong (S(E) \otimes S(F))_{\mathrm{Sym}_t}$, where N_{Sym_t} denotes the space of coinvariants of an A -module N , i.e. the quotient of N by the span of the elements $x - g \cdot x$, $x \in N$, $g \in \mathrm{Sym}_t$. Now let P, Q and ν be as in Section 1.1. Then the number of m -tuples of semi-standard tableaux with shapes determined by Q and weights determined by P is equal to the dimension of $\mathrm{Hom}_{\mathrm{Sym}_\nu}(S(E), S(F)) \cong (S(E) \otimes S(F))^{\mathrm{Sym}_\nu} \cong (S(E) \otimes S(F))_{\mathrm{Sym}_\nu}$, where $\mathrm{Sym}_\nu \leq \mathrm{Sym}_t$ is the Young subgroup associated to ν . For more details we refer to [11] and [10, Sect. 3].

Remarks 1. 1. One can of course also define $\nabla_{\mathrm{GL}_r}(E)$ as the span in $k[\mathrm{Mat}_{sr}]$ of all the bideterminants $(S_E | T)$ where T is a tableau of shape E and with entries $\leq r$. Then the action of GL_r comes from the right multiplication rather than from the left multiplication.

2. Let λ and μ be partitions with $\mu \subseteq \lambda$. Let r, r_1, s be integers ≥ 0 with $r_1, s \geq l(\lambda)$ and $r_1 \geq l(\mu) + r$ and put $r' = r_1 - r$. We embed $\mathrm{GL}_{r'} \times \mathrm{GL}_r$ in GL_{r_1} such that GL_r fixes the first r' basis vectors. Then one can embed $\nabla_{\mathrm{GL}_r}(\lambda/\mu)$ as a GL_r -submodule in $\nabla_{\mathrm{GL}_{r_1}}(\lambda)$. Indeed one can deduce from [6] that $\nabla_{\mathrm{GL}_r}(\lambda/\mu) \cong \mathrm{Hom}_{\mathrm{GL}_{r'}}(\Delta_{\mathrm{GL}_{r'}}(\mu), \nabla_{\mathrm{GL}_{r_1}}(\lambda)) \cong \nabla_{\mathrm{GL}_{r_1}}(\lambda)_{\mu}^{U_{r'}}$, where μ is considered as a weight for $T_{r'}$. One can also construct an explicit isomorphism as follows. Let $E \in \mathrm{Mat}_{r's}$ be the matrix whose first $\min(r', s)$ rows are those of the $s \times s$ identity matrix followed by $r' - s$ zero rows if $r' > s$. Then the comorphism of the morphism $A \mapsto \begin{bmatrix} E \\ A \end{bmatrix} : \mathrm{Mat}_{rs} \rightarrow \mathrm{Mat}_{r_1s}$ maps $\nabla_{\mathrm{GL}_{r_1}}(\lambda)_{\mu}^{U_{r'}}$

isomorphically onto $\nabla_{\mathrm{GL}_r}(\lambda/\mu)$. Combinatorially this is easy to understand: $\nabla_{\mathrm{GL}_{r_1}}(\lambda)^{U_{r'}}$ has a basis labelled by semi-standard tableaux of shape λ with entries $\leq r_1$ in which the entries $\leq r'$ occupy the boxes of μ and form the canonical tableau S_μ . These tableaux are clearly in one-one correspondence with the semi-standard tableaux of shape λ/μ with entries $\leq r$: just remove the μ -part and subtract r' from the entries of the resulting tableau of shape λ/μ .

3. We compare the approach of the present paper with that in [10, Sect. 3]. Let λ and μ be partitions of t with $l(\mu) \leq r$ and $l(\lambda) \leq s$ and let $\nu \in \Sigma_t$. Then we have that the space of coinvariants $(M(\mu) \otimes M(\lambda))_{\mathrm{Sym}_\nu}$ is isomorphic to the piece of multidegree ν of the weight space $k[\mathrm{Mat}_{rs}^m]_{(\mu, \lambda)}$, see [10, proof of Thm. 3] and also [2, Thm 3.7]. The permutation module $M(\mu)$ can be identified with the weight space $k[\mathrm{Mat}_{tr}]_{(1^t, \mu)}$ and similar for $M(\lambda)$. If k has characteristic 0, then $(S(\mu) \otimes S(\lambda))_{\mathrm{Sym}_\nu}$ embeds in $(M(\mu) \otimes M(\lambda))_{\mathrm{Sym}_\nu}$. In [10, Sect. 3] we worked with $S(\mu)$ and $S(\lambda)$ which can be thought of as spanned by bideterminants $(T|S_\mu)$, T a t -tableau of shape μ , and $(T|S_\lambda)$, T a t -tableau of shape λ . Actually, we mostly worked with skew versions of $S(\mu)$ and $S(\lambda)$. Only after [10, Prop. 3] we passed to coinvariants. In the present paper we work entirely inside the space of coinvariants which is the degree ν piece of $k[\mathrm{Mat}_{rs}^m]_{(\mu, \lambda)}$. This means that t -tableaux play almost no role, they are “replaced” by diagram mappings $\alpha : \mu \rightarrow \lambda$. The canonical tableaux S_μ and S_λ are now arbitrary tableaux S and T of shape μ and λ and we work with twisted bideterminants $(S|_\alpha T)$.

2. THE ACTION OF $\mathrm{GL}_r \times \mathrm{GL}_s$ ON SEVERAL $r \times s$ -MATRICES

Let λ, μ be partitions of t with $l(\mu) \leq r$ and $l(\lambda) \leq s$, let P, Q ordered tableaux of shapes λ and μ , both of weight $\nu \in \Sigma_t$ and $\alpha : \mu \rightarrow \lambda$ a diagram mapping such that $P \circ \alpha = Q$. Define $u_{P, Q, \alpha} \in k[\mathrm{Mat}_{rs}^m]^{U_r \times U_s}_{(\mu, \lambda)}$ by

$$u_{P, Q, \alpha} = \sum_{\pi \in C_\mu, \sigma \in C_\lambda} \mathrm{sgn}(\pi) \mathrm{sgn}(\sigma) \prod_{a \in \mu} x(Q(a))_{\pi(a)_1, \sigma(\alpha(a))_1}, \quad (1)$$

where b_1 is the row index of a box b . It was proved in [10, Thm. 4] that for suitable (ν, P, Q, α) these elements form a basis of the vector space $k[\mathrm{Mat}_{rs}^m]^{U_r \times U_s}_{(\mu, \lambda)}$ when k has characteristic 0.¹ More generally, we can consider for E and F skew shapes with t boxes, P, Q tableaux of shapes E and F , both of weight $\nu \in \Sigma_t$, $\alpha : F \rightarrow E$ a diagram mapping such that $P \circ \alpha = Q$, S a tableau of shape F with entries $\leq r$ and T a tableau of shape E with entries $\leq s$ the sum

$$\sum_{(\pi, \sigma) \in C_F \times C_E} \mathrm{sgn}(\pi) \mathrm{sgn}(\sigma) \prod_{a \in F} x(Q(a))_{S(\pi(a)), T(\sigma(\alpha(a)))}. \quad (2)$$

Note that we obtain (1) from (2) by taking S and T the canonical tableaux S_F and S_E .

¹In [10] we used the inverse rather than the transpose for the action of GL_r , which explains why we have $\pi(a)_1$ here rather than $r - \pi(a)_1 + 1$.

We will now show that (2) is in $\mathbb{Z}[\text{Mat}_{rs}^m] = \mathbb{Z}[(x(l)_{ij})_{lij}]$ divisible by the order of the subgroup

$$C_{P,Q,\alpha} = \{(\tau, \rho) \in C_F(Q) \times C_E(P) \mid \alpha \circ \tau \circ \alpha^{-1} = \rho\}$$

of $C_F \times C_E$, where $C_F(Q)$ is the stabiliser of Q in C_F and $C_E(P)$ is defined similarly. Note that

$$C_{P,Q,\alpha} \cong C_F(Q) \cap \alpha^{-1} C_E(P) \alpha \leq \text{Sym}(F) \cong \prod_{i=1}^m C_{Q^{-1}(i)} \cap \alpha_i^{-1} C_{P^{-1}(i)} \alpha_i$$

and that

$$C_{P,Q,\alpha} \cong \alpha C_F(Q) \alpha^{-1} \cap C_E(P) \leq \text{Sym}(E) \cong \prod_{i=1}^m \alpha_i C_{Q^{-1}(i)} \alpha_i^{-1} \cap C_{P^{-1}(i)}.$$

In each of the two lines above one may omit “(Q)” in $C_F(Q)$ or “(P)” in $C_E(P)$, but not both.

Lemma 1. *Each summand in (2) only depends on the left coset of (π, σ) modulo $C_{P,Q,\alpha}$.*

Proof. Let $(\pi_1, \sigma_1), (\pi_2, \sigma_2) \in C_F \times C_E$ and suppose $(\pi_2, \sigma_2) = (\pi_1 \circ \tau, \sigma_1 \circ \rho)$ for some $(\tau, \rho) \in C_{P,Q,\alpha}$. Then $\text{sgn}(\pi_1)\text{sgn}(\sigma_1) = \text{sgn}(\pi_2)\text{sgn}(\sigma_2)$, since $\text{sgn}(\tau) = \text{sgn}(\rho)$. Furthermore,

$$\begin{aligned} \prod_{a \in F} x(Q(a))_{S(\pi_2(a)), T(\sigma_2(\alpha(a)))} &= \prod_{a \in F} x(Q(a))_{S(\pi_1(\tau(a))), T(\sigma_1(\rho(\alpha(a))))} \\ &= \prod_{a \in F} x(Q(a))_{S((\tau(a))), T(\sigma_1(\alpha(\tau(a))))} \\ &= \prod_{a \in F} x(Q(\tau^{-1}(a)))_{S(\pi_1(a)), T(\sigma_1(\alpha(a)))} \\ &= \prod_{a \in F} x(Q(a))_{S(\pi_1(a)), T(\sigma_1(\alpha(a)))}. \end{aligned}$$

□

We now define the *twisted bideterminant* $(S |_{\alpha}^m T) \in k[\text{Mat}_{rs}^m]$ by

$$(S |_{\alpha}^m T) = \sum_{(\pi, \sigma)} \text{sgn}(\pi)\text{sgn}(\sigma) \prod_{a \in F} x(Q(a))_{S(\pi(a)), T(\sigma(\alpha(a)))}, \quad (3)$$

where the sum is over a set of representatives of the left cosets of $C_{P,Q,\alpha}$ in $C_F \times C_E$. To keep the notation manageable, we suppressed $(P$ and $) Q$ in $(S |_{\alpha}^m T)$. Clearly, if k has characteristic 0, then $(S |_{\alpha}^m T)$ equals (2) divided by $|C_{P,Q,\alpha}|$. Note that the product in (3) can also be written as

$$\prod_{a \in E} x(P(a))_{S(\pi(\alpha^{-1}(a))), T(\sigma(a))}.$$

In case $m = 1$, P and Q are constant equal to 1 and they play no role. We then omit P, Q and the superscript m in our notation and instead of $x(1)_{ij}$ we write x_{ij} . So

$$(S|_{\alpha} T) = \sum_{(\pi, \sigma)} \text{sgn}(\pi) \text{sgn}(\sigma) \prod_{a \in F} x_{S(\pi(a)), T(\sigma(\alpha(a)))}, \quad (4)$$

where the sum is over a set of representatives of the left cosets of $C_{\alpha} = \{(\tau, \rho) \in C_F \times C_E \mid \alpha \circ \tau \circ \alpha^{-1} = \rho\}$ in $C_F \times C_E$. Note that if $m = 1$, $E = F$ and $\alpha = \text{id}$ we get the ordinary bideterminant.

Remark 2. If X is a set of representatives for the left cosets of $\alpha C_F(Q) \alpha^{-1} \cap C_E(P)$ in C_E , then $C_F \times X$ is a set of representatives for the left cosets of $C_{P,Q,\alpha}$ in $C_F \times C_E$. If we concatenate all matrices in an m -tuple column-wise, then we obtain an isomorphism $k[\text{Mat}_{rs}^m] \cong k[\text{Mat}_{r,ms}]$ which maps $x(l)_{ij}$ to $x_{i,(l-1)s+j}$. Now we have

$$(S|_{\alpha}^m T) = \sum_{\sigma \in X} \text{sgn}(\sigma) (S|T^{\alpha,\sigma}),$$

where $T^{\alpha,\sigma}(a) = T(\sigma(\alpha(a))) + (Q(a) - 1)s$ for $a \in F$. Of course we could also work with a set \tilde{X} of representatives for the left cosets of $C_F(Q) \cap \alpha^{-1} C_E(P) \alpha$ in $\tilde{C}_F = \alpha^{-1} C_E \alpha$. Then the above sum would be over $\sigma \in \tilde{X}$ with $T^{\alpha,\sigma}(a) = T(\alpha(\sigma(a))) + (Q(a) - 1)s$ for $a \in F$.

Similarly, if X is a set of representatives for the left cosets of $C_F(Q) \cap \alpha^{-1} C_E(P) \alpha$ in C_F , then $X \times C_E$ is a set of representatives for the left cosets of $C_{P,Q,\alpha}$ in $C_F \times C_E$. If we concatenate all matrices in an m -tuple row-wise, then we obtain an isomorphism $k[\text{Mat}_{rs}^m] \cong k[\text{Mat}_{mr,s}]$ which maps $x(l)_{ij}$ to $x_{(l-1)r+i,j}$. Then we have

$$(S|_{\alpha}^m T) = \sum_{\pi \in X} \text{sgn}(\pi) (S^{\alpha,\pi} | T),$$

where $S^{\alpha,\pi}(a) = S(\pi(\alpha^{-1}(a))) + (P(a) - 1)r$ for $a \in E$. With \tilde{X} a set of representatives for the left cosets of $\alpha C_F(Q) \alpha^{-1} \cap C_E(P)$ in $\tilde{C}_E = \alpha C_F \alpha^{-1}$, the above sum would be over $\pi \in \tilde{X}$ with $S^{\alpha,\pi}(a) = S(\alpha^{-1}(\pi(a))) + (P(a) - 1)r$ for $a \in E$.

In the case of the twisted bideterminants $(S|_{\alpha} T)$ for a single matrix P and Q play no role, so $C_F(Q)$ and $C_E(P)$ can be replaced by C_F and C_E , and in the definitions of $T^{\alpha,\sigma}$ and $S^{\alpha,\pi}$ the terms containing Q or P should be omitted. The twisted bideterminants $(S|_{\alpha} T)$ are known as “shuffle-products”, and moving from the single matrix version of the first expression above to that of the second is called “overtake of the P-shuffle product onto the L-side”, see [3, Sect. 8-11].

The coordinate ring $k[\text{Mat}_{rs}^m]$ is \mathbb{N}_0^m -graded. Fix a multidegree $\nu \in \Sigma_t$. Then one can construct a good filtration

$$M_1 \supseteq M_2 \supseteq \cdots \supseteq M_{q+1} = 0$$

of the graded piece M_1 of degree ν of $k[\text{Mat}_{rs}^m]$ as follows. We use triples (P, Q, α) where P and Q are ordered tableaux of weight ν with shapes λ of length $\leq s$ and μ of length $\leq r$ say, and $\alpha : \mu \rightarrow \lambda$ is in a set of (admissible) representatives for the m -tuples of special semi-standard tableaux with shapes determined by Q and weights determined by P . See Section 1.1.

Theorem 1. *We can enumerate all the triples (P, Q, α) as above:*

$$(P_1, Q_1, \alpha^1), (P_2, Q_2, \alpha^2), \dots, (P_q, Q_q, \alpha^q),$$

λ^i the shape of P_i , μ^i the shape of Q_i , such that for all i the span M_i of all twisted bideterminants $(S|_{\alpha^j}^m T)$, $j \geq i$, S of shape μ^j with entries $\leq r$, T of shape λ^j with entries $\leq s$, is $\mathrm{GL}_r \times \mathrm{GL}_s$ -stable and we have an isomorphism

$$(S|_{\mu^i} S) \otimes (T|_{\lambda^i} S) \mapsto (S|_{\alpha^i}^m T) \bmod M_{i+1} : \nabla_{\mathrm{GL}_r}(\mu^i) \otimes \nabla_{\mathrm{GL}_s}(\lambda^i) \xrightarrow{\sim} M_i/M_{i+1}.$$

Furthermore, the twisted bideterminants $(S|_{\alpha^j}^m T)$, $1 \leq j \leq q$, S and T as above and in addition semi-standard, form a basis of the graded piece of degree ν of $k[\mathrm{Mat}_{rs}^m]$.

Proof. We use the isomorphism $k[\mathrm{Mat}_{rs}^m] \cong k[\mathrm{Mat}_{mr,s}]$, see Remark 2. Let t be an integer ≥ 0 . We start with the well-known (descending) $\mathrm{GL}_{mr} \times \mathrm{GL}_s$ -filtration of the piece of degree t of $k[\mathrm{Mat}_{mr,s}]$ with sections isomorphic to

$$\nabla_{\mathrm{GL}_{mr}}(\lambda^i) \otimes \nabla_{\mathrm{GL}_s}(\lambda^i). \quad (5)$$

Here the λ^i are the partitions of t of length $\leq \min(mr, s)$. The isomorphisms to the sections of the filtration are given by

$$(S|_{\lambda^i} S) \otimes (T|_{\lambda^i} S) \mapsto (S|T) \text{ modulo the } (i+1)\text{-th filtration space.}$$

After restricting the left multiplication action to GL_r^m we can decompose the above filtration according to the multidegree in \mathbb{N}_0^m . From now on we focus on the piece of multidegree $\nu \in \Sigma_t$. By repeatedly applying [1, Thm. II.4.11] (see also [8, Thm. 1.4] and Remark 2 after it) to $\nabla_{\mathrm{GL}_{mr}}(\lambda^i)$ we can refine the above filtration to a filtration with sections isomorphic to

$$\left(\bigotimes_{j=1}^m \nabla_{\mathrm{GL}_r}(P_i^{-1}(j)) \right) \otimes \nabla_{\mathrm{GL}_s}(\lambda^i). \quad (6)$$

Here the λ^i are suitably redefined, the P_i go through all ordered tableaux of shape λ^i with weight ν , and the Levi GL_r^m acts on the first factor. The section-isomorphism of [1, Thm. II.4.11] is given by shifting the numbers in each tableau of shape $P_i^{-1}(j)$ by $(j-1)r$, so the result has its entries in $(j-1)r + \{1, \dots, r\}$, and then piecing the resulting tableaux of shapes $P_i^{-1}(j)$ together according to P_i to a tableau of shape λ^i . Now we restrict the first factor of (6) to the diagonal copy of GL_r in GL_r^m and we have

$$\bigotimes_{j=1}^m \nabla_{\mathrm{GL}_r}(P_i^{-1}(j)) \cong \nabla_{\mathrm{GL}_r}(E_{P_i}), \quad (7)$$

where for P an ordered tableau with entries $\leq m$ we define $E_P = E_{(P^{-1}(1), \dots, P^{-1}(m))}$ and for an m -tuple (D_1, \dots, D_m) of skew Young diagrams

$$E_{(D_1, \dots, D_m)} = \begin{array}{c} D_1 \\ \cdot \cdot \\ D_m \end{array}$$

where each row or column contains boxes from at most one skew tableau D_j . Now we apply [8, Thm. 1.5] and we can refine our previous filtration to a filtration with sections

$$\nabla_{\text{GL}_r}(\mu^i) \otimes \nabla_{\text{GL}_s}(\lambda^i).$$

Here the λ^i are again suitably redefined and the μ^i have length $\leq r$. Furthermore, the labelling is coming from triples $(P, \mu, \bar{\alpha})$ where P is an ordered tableau of weight ν , μ a partition of t and $\bar{\alpha} : \mu \rightarrow E_P$ goes through a set of admissible representatives for the special semi-standard tableaux of shape μ and weight the tuple of row lengths of E_P . These triples are in one-one correspondence with the triples (P, Q, α) mentioned earlier.

We now have to check that our filtration is indeed given by spans of twisted bideterminants. From Remark 2 it is clear that under the section-isomorphism (5) the element $(S|_{\alpha}^m S_{\lambda^i}) \otimes (T| S_{\lambda^i})$, S of shape μ with entries $\leq r$, $\alpha : \mu \rightarrow \lambda^i$, T of shape λ^i with entries $\leq s$, is mapped to $(S|_{\alpha}^m T)$ modulo the $(i+1)$ -th filtration space. So it now suffices to show that at “stage (7)” the elements $(S|_{\alpha}^m S_{\lambda^i})$ correspond under the isomorphism (7) combined with the section isomorphism of [1, Thm. II.4.11] to the elements defining the filtration of $\nabla_{\text{GL}_r}(E_{P_i})$ from [8, Thm. 1.5].

For this we focus on one particular i which we suppress in the notation. If $\alpha : \mu \rightarrow \lambda$ is an admissible representative of an m -tuple of special semi-standard tableaux, then the diagram mapping $\bar{\alpha} : \mu \rightarrow E_P$ whose restrictions $Q^{-1}(j) \rightarrow P^{-1}(j)$ are the same as those of α , is an admissible representative of the special semi-standard tableau $T = S_{E_P} \circ \bar{\alpha}$ of shape μ . The elements defining the filtration of $\nabla_{\text{GL}_r}(E_P)$ from the proof of [8, Thm. 1.5] are $(S|_{\bar{\alpha}} S_{E_P})$, S of shape μ with entries $\leq r$. Here one should bear in mind that in [8] the bideterminants are formed row-wise rather than column-wise, and that there $\bar{\alpha}^{-1}$ is used rather than $\bar{\alpha}$: the map f_T on page 93 of [8] satisfies (after transposing) $T \circ f_T = S_{E_P}$, and it corresponds to the inverse of our $\bar{\alpha}$.² By Remark 2 we have

$$(S|_{\bar{\alpha}} S_{E_P}) = \sum_{\pi \in X} \text{sgn}(\pi) (S^{\bar{\alpha}, \pi} | S_{E_P}),$$

where X is a set of representatives for the left cosets of $C_{\mu} \cap \bar{\alpha}^{-1} C_{E_P} \bar{\alpha}$ in C_{μ} and $S^{\bar{\alpha}, \pi}(a) = S(\pi(\bar{\alpha}^{-1}(a)))$ for $a \in E_P$. Now we have $C_{\mu} \cap \bar{\alpha}^{-1} C_{E_P} \bar{\alpha} = C_{\mu}(Q) \cap \alpha^{-1} C_{\lambda}(P) \alpha$, so, by Remark 2 we have for the same set X

$$(S|_{\alpha}^m S_{\lambda}) = \sum_{\pi \in X} \text{sgn}(\pi) (S^{\alpha, \pi} | S_{\lambda}),$$

where $S^{\alpha, \pi}(a) = S(\pi(\alpha^{-1}(a))) + (P(a) - 1)r$ for $a \in \lambda$. Under the isomorphism (7) combined with the section isomorphism of [1, Thm. II.4.11] $S^{\bar{\alpha}, \pi}$ corresponds to $S^{\alpha, \pi}$, that is, $(S^{\bar{\alpha}, \pi} | S_{E_P})$ is mapped to $(S^{\alpha, \pi} | S_{\lambda})$ modulo the filtration space

²Actually the $\bar{\alpha}$ corresponding to the f_T from [8] are the (unique) special representatives of the special semi-standard tableaux T of shape μ and weight the tuple of row lengths of E_P , but it is clear that the arguments there work for any choice of admissible representatives $\bar{\alpha}$. Furthermore, it is clear from the proof of Claim 2 on p 94 of [8] that the filtration of $\nabla_{\text{GL}_r}(E_P)$ does not depend on the choice of representing $\bar{\alpha}$'s.

labelled by “the next P ”. So, by the above two equations, $(S|_{\alpha} S_{E_P})$ is mapped to $(S|_{\alpha}^m S_{\lambda})$ modulo the filtration space labelled by the next P . \square

Corollary 1. *Let λ, μ be a partitions of t with $l(\mu) \leq r$ and $l(\lambda) \leq s$ and let $\nu \in \Sigma_t$. Then the elements $(S_{\mu}|_{\alpha}^m S_{\lambda})$, P, Q ordered tableaux of shapes λ and μ , both of weight ν , and α in a set of representatives for the m -tuples of special semi-standard tableaux with shapes determined by Q and weights determined by P , form a basis of the piece of degree ν of $k[\text{Mat}_{rs}^m]_{(\mu, \lambda)}^{U_r \times U_s}$.*

Proof. It is easy to see, using Remark 2 for example, that the elements $(S_{\mu}|_{\alpha}^m S_{\lambda})$ are highest weight vectors of the given weight. Furthermore, they are linearly independent by Theorem 1. On the other hand it follows from standard properties of good filtrations, see [9, Prop. II.4.13], that the dimension of $k[\text{Mat}_{rs}^m]_{(\mu, \lambda)}^{U_r \times U_s}$ is equal to the number of sections $\nabla_{\text{GL}_r}(\mu^i) \otimes \nabla_{\text{GL}_s}(\lambda^i)$ with $(\lambda_i, \mu_i) = (\lambda, \mu)$ in a good filtration of $k[\text{Mat}_{rs}^m]$. But this is equal to the number of elements of our linearly independent set. \square

Finally we give a version for the above corollary for the $\text{GL}_r \times \text{GL}_s$ -action on $k[\text{Mat}_{rs}^m]$ defined by $((A, B) \cdot f)(\underline{X}) = f((A^{-1}X_i B)_{1 \leq i \leq m})$, that is, we twist the GL_r -action we considered previously with the inverse transpose. We define the *anti-canonical tableau* \tilde{S}_{μ} of shape μ by $\tilde{S}_{\mu}(a) = r - a_1 + 1$, for $a \in \mu$ where a_1 is the row index of a . For a tuple μ of integers of length $\leq r$ we denote by μ^{rev} the reverse of the r -tuple obtained from μ by extending it with zeros.

Corollary 2. *Let λ, μ be partitions of t with $l(\mu) \leq r$ and $l(\lambda) \leq s$ and let $\nu \in \Sigma_t$. Then the elements $(\tilde{S}_{\mu}|_{\alpha}^m S_{\lambda})$, P, Q ordered tableaux of shapes λ and μ , both of weight ν , and α in a set of representatives for the m -tuples of special semi-standard tableaux with shapes determined by Q and weights determined by P , form a basis of the piece of degree ν of $k[\text{Mat}_{rs}^m]_{(-\mu^{\text{rev}}, \lambda)}^{U_r \times U_s}$.*

Remarks 3. 1. We now extract from the proof of Theorem 1 how the triples (P, Q, α) are enumerated. First we order the P 's by identifying each P with the tuple of Young diagrams (i.e. partitions) $P^{-1}(\{1, \dots, m-i\})_{0 \leq i \leq m-1}$ and ordering these lexicographically, where the partitions are themselves also ordered lexicographically. For a fixed P we order the pairs (Q, α) as follows. For each i we let S_i be the tableau obtained by shifting the entries of $S_{P^{-1}(i)} \circ \alpha_i$ by $\sum_{j=0}^{i-1} r_j$, where r_j is the number of rows of $P^{-1}(j)$. Here the α_i are defined as in Section 1.1. Let $S_{Q, \alpha}$ be the tableau of the same shape as Q obtained by piecing the S_i together according to Q . Then we say that $(Q^1, \alpha^1) > (Q^2, \alpha^2)$ if the standard enumeration of S_{Q^1, α^1} is lexicographically less than that of S_{Q^2, α^2} . Now we order the triples (P, Q, α) lexicographically by first comparing the P -component and then the (Q, α) -component. Finally, we enumerate the triples (P, Q, α) in decreasing order.

2. We give a characteristic free version of [10, Thm. 3], and an interpretation. Let E and F be skew Young diagrams with t boxes. Let r be \geq the number of rows of F and let s be \geq the number of rows of E , then the twisted bideterminants $(S_F|_{\alpha} S_E) \in k[\text{Mat}_{rs}]$ where α goes through a set of admissible representatives of special semistandard tableaux of shape F and weight the tuple of row lengths of E , are linearly independent.

This can be deduced from [8] as follows. Write $F = \mu/\tilde{\mu}$ and take \overline{E} to be E with $\tilde{\mu}$ above and to the right of it in such a way that they have no rows or columns in common. We use the definition of Schur modules from Remark 1.1 which uses the right multiplication action. If we combine this with Remark 1.2 we obtain an isomorphism $\nabla_{\mathrm{GL}_s}(F) \xrightarrow{\sim} \nabla_{\mathrm{GL}_{s_1}}(\mu)_{\tilde{\mu}}^{U_{s'}}$ where $s_1 = s' + s$. By Remark 2 this isomorphism maps $(S_F|_{\alpha} S_E)$ to $(S_{\mu}|_{\overline{\alpha}} S_{\overline{E}})$ where $\overline{\alpha} : \mu \rightarrow \overline{E}$ is given by $\overline{\alpha}|_F = \alpha$ and $\alpha|_{\tilde{\mu}} = \mathrm{id}$. For α as above, $\overline{\alpha}$ goes through a set of representatives for the special tableaux of shape μ and weight the tuple of row lengths of \overline{E} . Since the elements $(S_{\mu}|_{\overline{\alpha}} S_{\overline{E}})$ are linearly independent by the proof of [8, Thm. 1.5], the result follows.

Now we give two interpretations of this result. Firstly, the span of the above bideterminants can be seen as $k \otimes_{\mathbb{Z}} N_{\mathbb{Z}}$, where $N_{\mathbb{Z}}$ is the intersection of $(S_{t,\mathbb{Q}}(E) \otimes S_{t,\mathbb{Q}}(F))_{\mathrm{Sym}_t}$ with the obvious \mathbb{Z} -form of $(M_{t,\mathbb{Q}}(E) \otimes M_{t,\mathbb{Q}}(F))_{\mathrm{Sym}_t}$. Secondly, when $r \geq$ the number of rows of F , this span can be identified with $\mathrm{Hom}_{\mathrm{GL}_r}(\Delta_{\mathrm{GL}_r}(F), \nabla_{\mathrm{GL}_r}(E))$. Indeed we have by [8, Thm. 1.1(g)]

$$\begin{aligned} D_L(U, S_F) \cdot (S_F|T_F) &= (\boxed{U}|T_F), \\ D_L(U, S_F) \cdot (S_F|_{\alpha} S_E) &= (\boxed{U}|_{\alpha} S_E). \end{aligned}$$

Here we adapted the notation to that of our paper: We use T_E and S_E instead of T_E^* and T_E . Furthermore, we associate bideterminants column-wise rather than row-wise, so the bideterminants of shape λ from [8] have shape λ' in our notation, \boxed{U} means sum over all tableaux *row* equivalent to U etc. So the module $\Delta_{\mathrm{GL}_r}(F)$ is cyclic generated by $(S_F|T_F)$ and the homomorphisms

$$(\boxed{U}|T_F) \mapsto (\boxed{U}|_{\alpha} S_E) : \Delta_{\mathrm{GL}_r}(F) \rightarrow \nabla_{\mathrm{GL}_r}(E)$$

are linearly independent, since their images of the generator $(S_F|T_F)$ are linearly independent by the above result. We have seen in Section 1.2 that their number is equal to the dimension of $\mathrm{Hom}_{\mathrm{GL}_r}(\Delta_{\mathrm{GL}_r}(F), \nabla_{\mathrm{GL}_r}(E))$, so they must form a basis. In general the above homomorphisms will always span $\mathrm{Hom}_{\mathrm{GL}_r}(\Delta_{\mathrm{GL}_r}(F), \nabla_{\mathrm{GL}_r}(E))$ by [7, Prop. 1.5(i)] applied to $\lambda = t\varepsilon_1$, $G = \mathrm{GL}_{r'}$ for some $r' \geq$ the number of rows of F and Σ the root system of GL_r . For dimension reasons, see Section 1.2, these homomorphisms will then also form a basis when $r \geq$ the number of rows of E .

3. Assume $r = r_1 + \cdots + r_m$ for certain integers $r_j > 0$. By similar arguments as in the proof of Theorem 1 one can construct a good $(\prod_{j=1}^m \mathrm{GL}_{r_j}) \times \mathrm{GL}_s$ -filtration of the degree ν piece of $k[\mathrm{Mat}_{rs}]$ using a spanning set labelled by triples $(\lambda, (\mu^1, \dots, \mu^m), \alpha)$, where λ is a partition of $t = |\nu|$ of length $\leq s$, (μ^1, \dots, μ^m) is an m -tuple of partitions with μ^j of length $\leq r_j$ and $|\mu^1| + \cdots + |\mu^m| = t$, and where $\alpha : E_{(\mu^1, \dots, \mu^m)} \rightarrow \lambda$ goes through a set of admissible representatives for the special semi-standard tableaux of shape $E_{(\mu^1, \dots, \mu^m)}$ and weight λ . These triples are in one-one correspondence with the triples $(P, (\mu^1, \dots, \mu^m), (\alpha_1, \dots, \alpha_m))$, where P is an ordered tableau of weight ν , (μ^1, \dots, μ^m) is an m -tuple of partitions with μ_j of length $\leq r_j$ and $|\mu^1| + \cdots + |\mu^m| = t = |\nu|$, and each $\alpha_j : \mu_j \rightarrow P^{-1}(j)$ goes through a set of admissible representatives for the special semi-standard tableaux of shape μ_j and weight the tuple of row lengths of $P^{-1}(j)$.

The filtration spaces are spanned by twisted bideterminants $(S|_\alpha T)$, where S is of shape $E_{(\mu^1, \dots, \mu^m)}$ with entries $\leq r$, satisfying $S^{-1}((\sum_{l=1}^{j-1} r_l + \{1, \dots, r_j\})) = \mu^j \subseteq E_{(\mu^1, \dots, \mu^m)}$ for all j , T is of shape λ with entries $\leq s$ and $\alpha : E_{(\mu^1, \dots, \mu^m)} \rightarrow \lambda$ is as above.

3. HIGHEST WEIGHT VECTORS FOR THE CONJUGATION ACTION OF GL_n ON POLYNOMIALS

Firstly, let us introduce some further notation. For n a natural number and λ, μ partitions with $l(\lambda) + l(\mu) \leq n$, define the descending n -tuple

$$[\lambda, \mu] := (\lambda_1, \dots, \lambda_{l(\lambda)}, 0, \dots, 0, -\mu_{l(\mu)}, \dots, -\mu_1).$$

The group GL_n acts on Mat_n via the conjugation action, given by $S \cdot A = SAS^{-1}$ and therefore on the coordinate ring $k[\mathrm{Mat}_n]$ via $(S \cdot f)(A) = f(S^{-1}AS)$. Note that the nilpotent cone $\mathcal{N}_n = \{A \in \mathrm{Mat}_n \mid A^n = 0\}$ is under this action a GL_n -stable closed subvariety of Mat_n . We denote the algebra of invariants of $k[\mathrm{Mat}_n]$ under the conjugation action by $k[\mathrm{Mat}_n]^{\mathrm{GL}_n}$. It is well-known that this is the polynomial algebra in the traces of the exterior powers of the matrix.

Now let r, s be integers ≥ 0 with $r + s \leq n$. We let $\mathrm{GL}_r \times \mathrm{GL}_s$ act on $k[\mathrm{Mat}_{rs}^m]$ as at the end of Section 2: we use the inverse rather than the transpose to define the action of GL_r . For a matrix M denote by $M_{r|s}$ the lower left $r \times s$ corner of M . For m an integer ≥ 2 we define the map $\varphi_{r,s,n,m} : \mathrm{Mat}_n \rightarrow \mathrm{Mat}_{rs}^m$ by

$$\varphi_{r,s,n,m}(X) = (X_{r|s}, (X^2)_{r|s}, \dots, (X^m)_{r|s}).$$

The restriction of this map to the nilpotent cone \mathcal{N}_n will be denoted by the same symbol. In [10] the following result was proved.

Theorem 2 ([10, Thm. 1]). *Let $\chi = [\lambda, \mu]$ be a dominant weight in the root lattice, $l(\mu) \leq r$, $l(\lambda) \leq s$, $r + s \leq n$. Then the pull-back map*

$$k[\mathrm{Mat}_{rs}^{n-1}]_{(-\mu^{\mathrm{rev}}, \lambda)}^{U_r \times U_s} \rightarrow k[\mathcal{N}_n]_\chi^{U_n}$$

along $\varphi_{r,s,n,n-1} : \mathcal{N}_n \rightarrow \mathrm{Mat}_{rs}^{n-1}$ is surjective.

Combining this with Corollary 2 to Theorem 1 we obtain

Corollary 3. *Let $\chi = [\lambda, \mu]$ be a dominant weight in the root lattice, $l(\mu) \leq r$, $l(\lambda) \leq s$, $|\lambda| = |\mu| = t$, $r + s \leq n$. Then the pull-backs of the elements $(\tilde{S}_\mu|_\alpha^m S_\lambda)$, ν, P, Q, α as in Cor. 2 to Thm. 1, along $\varphi_{r,s,n,n-1} : \mathcal{N}_n \rightarrow \mathrm{Mat}_{rs}^{n-1}$ span the vector space $k[\mathcal{N}_n]_\chi^{U_n}$.*

Next we recall the following instance of the graded Nakayama Lemma from [10].

Lemma 2 ([10, Lem. 1]). *Let $f_1, \dots, f_l \in k[\mathrm{Mat}_n]_\chi^{U_n}$ be homogeneous. If the restrictions $f_1|_{\mathcal{N}_n}, \dots, f_l|_{\mathcal{N}_n}$ span $k[\mathcal{N}_n]_\chi^{U_n}$, then f_1, \dots, f_l span $k[\mathrm{Mat}_n]_\chi^{U_n}$ as a $k[\mathrm{Mat}_n]^{\mathrm{GL}_n}$ -module. The same holds with “span” replaced by “form a basis of”.*

Combining Corollary 3 and Lemma 2 we finally obtain

Corollary 4. *Let $\chi = [\lambda, \mu]$ be a dominant weight in the root lattice, $l(\mu) \leq r$, $l(\lambda) \leq s$, $|\lambda| = |\mu| = t$, $r+s \leq n$. Then the pull-backs of the elements $(\tilde{S}_\mu |_\alpha^m S_\lambda)$, ν, P, Q, α as in Cor. 2 to Thm. 1, along $\varphi_{r,s,n,n-1} : \text{Mat}_n \rightarrow \text{Mat}_{rs}^{n-1}$ span the $k[\text{Mat}_n]^{\text{GL}_n}$ -module $k[\text{Mat}_n]_\chi^{U_n}$.*

Remarks 4. 1. Note that pulling the $(\tilde{S}_\mu |_\alpha^m S_\lambda)$ back just amounts to interpreting $x(Q(a))_{ij}$ as the (i, j) -th entry of the $Q(a)$ -th matrix power and replacing $r - a_1 + 1$ by $n - a_1 + 1$. In particular, these pulled-back functions don't depend on the choice of r and s .

2. One obtains a bigger, "easier" spanning set by allowing arbitrary P, Q of weight ν and arbitrary bijections $\alpha : \mu \rightarrow \lambda$ with $P \circ \alpha = Q$.
